1. Detailed panel-comment compliance matrix

No.	Panel comment / area	Evidence in the main manuscript	Status	Required action
1	Chapter 1 – Introduction: Ground the problem in the actual operating conditions of Shoelotskey rather than relying mainly on generic claims about small businesses.	The introduction discusses manual recording, fragmented records, and operational inefficiencies. However, it still contains broad claims and a research-gap argument that need stronger supporting evidence.	Partial	Use documented interviews, observations, and business records to substantiate the specific operational problems. Cite appropriate literature for broader claims.
2	Problem Statement: Establish the actual problems identified through the pre-assessment.	The main manuscript lists retrieval times of 15–30 minutes, report preparation of 4–6 hours monthly, and 280–300 monthly service orders. The annotated revision describes a more evidence-based pre-assessment.	Partial	Reconcile the baseline figures with the actual records and the revised Chapter 4 measurements. Explain differences in measurement procedures instead of presenting inconsistent baselines.
3	Conceptual Framework: Revise the IPO framework to show evaluation and feedback explicitly.	The main manuscript describes Input, Process, Output, and a feedback loop. The annotated version adds a separate Evaluation component for ISO/IEC 25010, TAM, machine-learning metrics, and manual-versus-digital comparisons.	Not aligned	Replace the framework in the main manuscript with the approved diagram and ensure the narrative explains every component consistently.
4	Specific Objective 1: Conduct a comparative analysis of the manual and digital systems using record accessibility, retrieval time, and accuracy.	The main manuscript retains the earlier objective of developing the system and reducing retrieval time from 15–30 minutes to under five minutes.	Not aligned	Replace the old objective with the comparative-analysis objective. Present corresponding baseline and digital results, the measurement procedure, and evidence of data accuracy.

5	Specific Objective 2: Evaluate the Random Forest Regressor using MAE, RMSE, \(R^2\), and prediction tolerances of ±1, ±2, ±3, and ±5 days.	The main manuscript still states a target of 85% or higher prediction accuracy against manual estimates and discusses MAE without establishing the complete revised evaluation.	Not aligned	Replace the unsupported percentage-accuracy target with the approved metrics. Report the actual values, test-data procedure, and limitations.
6	Historical prediction target: Evaluate the feasibility and limitations of the historical Order-to-Claim target using actual records.	The annotated Sir Alojado copy explains that historical records contain Date Received and Claimed Date but lack a reliable Ready-for-Release timestamp. The main manuscript does not adequately document this distinction.	Not aligned	Distinguish Order-to-Claim turnaround from actual Received-to-Ready-for-Release duration. Explain what the historical model can and cannot predict.
7	Specific Objective 3: Measure dashboard impact on reporting efficiency, access to business information, and decision-making.	The main manuscript promises automated reporting and a reduction in report preparation time from 4–6 hours to under one hour, but the available Chapter 4 text does not establish the corresponding comparative results.	Partial	Report actual report-generation times and describe how dashboard usefulness and decision-support perceptions were measured. Avoid claiming improvement without supporting data.
8	Specific Objective 4: Align software-quality evaluation with the characteristics specified in the panel's revised objectives.	The main manuscript uses the earlier list of functional suitability, performance efficiency, usability, reliability, security, maintainability, and portability. The annotated version expands the list to nine characteristics.	Not aligned	Use one consistent, explicitly justified evaluation model and set of characteristics in the objectives, questionnaire, methodology, tables, and discussion.
9	Specific Objective 5: Assess user acceptance using TAM.	The main manuscript identifies perceived usefulness, perceived ease of use, behavioral intention, and actual system use.	Partial	Retain these constructs if they remain in the approved objectives, but verify that the questionnaire items, respondents, analysis, and

				Chapter 4 findings correspond to each construct.
10	Specific Objective 6: Base future recommendations on the findings.	The main manuscript states that future improvements will be recommended, but the supplied version does not provide a complete findings-to-recommendations trail.	Partial	Link every major recommendation to a documented system limitation, evaluation finding, or user requirement.
11	Analysis of the Existing System: Explain the actual workflow and the limitations of manual procedures.	The main manuscript includes an existing-system analysis describing paper records, spreadsheets, manual status updates, and retrieval problems.	Substantially addressed	Retain the section, but ensure the figures and baseline measurements agree with the evidence used in Chapter 4.
12	Data Flow Diagram Level 1: Address the panel's handwritten annotations on the process diagram.	The main manuscript contains a Level 1 DFD and accompanying process descriptions. The small handwritten annotations in the reviewer's scan are not sufficiently legible to verify every requested correction.	Unverified	Check the marked diagram against the final DFD. Verify process numbering, data stores, external entities, and data-flow labels, and ensure consistency with the actual system modules.
13	Organizational Chart and respondents: Clarify who the intended users are and how IT experts are selected.	The main manuscript describes a proposed population of the owner and five employees, plus selected IT experts, largely in future tense. The annotated version specifies six Shoelotskey personnel and five IT experts.	Not aligned	Establish the actual number of participating owners, staff, and experts. Correct the sampling description, inclusion criteria, organizational chart, respondent table, and all references to sample size.
14	Comparative record-retrieval testing: Support the claimed improvement with documented measurements.	The annotated Sir Alojado copy shows a 10-trial comparison with a mean manual retrieval time of 5.20 minutes and digital retrieval time of 0.41 minutes, a reported reduction of	Partial	Include the complete table in the final manuscript, verify the calculations and trial procedure, and explain why the baseline differs from the

		92.12%. The main manuscript's earlier baseline is 15–30 minutes, so the figures require reconciliation.		original estimate. Preserve test records as supporting evidence.
15	Machine-learning results and limitations: Interpret the historical model's predictive performance honestly.	The annotated Sir Alojado copy reports MAE of 6.62 days, RMSE of 8.45 days, a negative \(R^2\), and only 42.3% of predictions within ±5 days. These results indicate that the historical model was not reliable enough to replace the business-rule estimate. The main manuscript does not show these findings in its corresponding evaluation section.	Not aligned	Include the actual results and explain the target limitation. Do not claim 85% accuracy or operational reliability unless a separate, valid evaluation supports that conclusion.
16	ISO/IEC 25010 expert assessment: Make the evaluation table and interpretation consistent.	The annotated Sir Alojado copy includes five IT experts' ratings, means, standard deviations, and interpretations, with technical tests described separately from perception-based ratings. The main manuscript does not contain the corresponding complete results in its supplied Chapter 4.	Not aligned	Include all approved quality characteristics, item-level scores, summary calculations, interpretation criteria, and expert qualifications. Distinguish subjective expert ratings from objective technical test results.
17	Technical performance evidence: Substantiate statements about speed and system responsiveness.	The annotated copy discusses separate objective technical tests and includes an expert observation of approximately 1.2 seconds for synchronous prediction. The main manuscript's methodology does not provide a complete reproducible test report.	Partial	Provide the actual test conditions, trial counts, expected and observed outcomes, response times, and pass/fail criteria. Do not treat an expert observation as a substitute for systematic testing.

The comparisons above are based on the main manuscript's Chapter 1 objectives and Chapter 4 methodology, together with the annotated objective revisions and marked evaluation pages in the two panel documents.

2. Critical discrepancies that must be corrected before approval

A. Objectives and Chapter 4 results are not synchronized.

The main manuscript still uses the 85% prediction-accuracy target, while the panel-marked version replaces it with regression metrics and tolerance analysis. The final manuscript must use the approved objectives and provide matching results for each one.

B. The machine-learning target needs an explicit limitation statement.

Order-to-Claim time includes the interval before the customer claims the shoes. It is not necessarily the actual service-processing duration. The annotated review recognizes this problem, but the main manuscript must carry the distinction into its methodology, results, conclusions, and recommendations.

C. The respondent count is inconsistent.

The main manuscript alternates between one owner and five staff, and even contains conflicting participant counts in its data-gathering description. The annotated version specifies two owners and four staff, with five IT experts. The final methodology and respondent tables must reflect the actual participants—not merely the intended population.

D. The claimed improvement in record retrieval requires a reconciled baseline.

The original Chapter 1 reports 15–30 minutes, while the annotated comparison table reports a manual mean of 5.20 minutes. These could reflect different tasks or measurement methods, but the manuscript must explain that distinction. Otherwise, the comparison risks appearing inconsistent or methodologically weak.

E. Software-quality ratings must be distinguished from technical test results.

Expert ratings such as “Highly Acceptable” measure perceptions under the stated evaluation instrument. They do not independently prove measured response time, reliability under load, or formal compliance with a software-quality standard. Both forms of evidence should be reported separately.

3. Additional methodological issues found in the main manuscript

These are important issues that needs to reconcile.

- Future-tense methodology: The main manuscript says respondents “will consist” of participants and experts and that evaluation “will be used,” although the project is presented as a completed capstone. Revise to past tense wherever the activities have actually been completed.
- Participant-count errors: The data-gathering section states “one (1) business owner and five (4) staff members” and later refers to “six (5) participants.” These are contradictory and must be corrected.
- Machine-learning evaluation: The statistical-treatment section emphasizes MAE, but the revised objectives require MAE, RMSE, R^2, and prediction-tolerance analysis. The methods and results must use the same metrics.
- Questionnaire alignment: The ISO/IEC 25010 and TAM questionnaires should be checked item by item against the approved constructs. Each reported mean must be traceable to the appropriate instrument and respondent group.
- Conclusion and recommendation alignment: Each conclusion should answer a specific objective using the actual findings. Recommendations must not claim that the machine-learning model is reliable if its reported evaluation does not support that claim.

4. Recommended order of revision

Revision checklist

1. Reconcile and finalize the six objectives
2. Use the revised objectives from the panel-marked version as the controlling version, subject to confirmation of the panel’s final approval.
3. Correct the respondent and sampling methodology
4. Confirm actual participants, dates, expert qualifications, sampling method, and respondent counts.
5. Integrate the complete Chapter 4 results
6. Include the record-retrieval comparison, ML metrics, dashboard/reporting evaluation, ISO/IEC 25010 results, TAM results, and technical tests.
7. Align the framework, diagrams, and instruments

8. Update the conceptual framework, DFD, organizational chart, and questionnaires to match the implemented system and approved objectives.
9. Rewrite conclusions and recommendations
10. Derive each conclusion from its corresponding result and acknowledge the ML target and data limitations.
11. Conduct a final consistency audit
12. Check all figures, tables, calculations, citations, tense, terminology, and cross-references.
